### Abstract

The characteristics of the profile of activities and performance of the badminton game can be used as helpful tools for an adequate elaboration of competitive training. Although the literature provides a large number of studies that describe the profile of activities and game performance in world-class badminton athletes, just a few focus on junior players. This study identified the characteristics of the game profile and performance of junior badminton players. The sample consisted of 124 games from the 5 types of events (singles and doubles) of the 28th Pan American Junior Championships 2019 from the under-13 to under-19 categories starting from the quarterfinals, totaling 9.847 rallies from 277 games. The results showed that the duration of the rally is shorter in men's doubles and mixed doubles than in other events ( $p \leq 0.001$ ). The female single's event, in general, presented a longer rest time between rallies ( $p \leq 0.001$ ). In all events, players sought to force their opponents to make mistakes ( $p \leq 0.001$ ). This information can be useful for the development of specific training for each type of event, with the reenactment of the different time scenarios characteristic of the match and the activity profile.

**Keywords:** performance analysis, young players, match analysis, sports training, racket sports.

### Introduction

For the spectator, a badminton match can be fascinating. In fractions of seconds, players alternately hit the shuttlecock, moving around their playing area in a variety of steps, jumping, turning, lunging until they get the ideal moment to finish the point or force their opponent to miss, and recovering themselves briefly to start all over again until finishing the game (Manrique & González-Badillo, 2003; Valldecabres et al., 2017). When the characteristics of the game activity and performance profile are known, it is possible to structure teaching-learning-training processes that may result in better sports performance (Aburachid et al., 2018; Gawin et al., 2015). Profile characterization is understood here as technical actions such as the number and types of strokes, for example (Chiminazzo et al., 2018) and performance can be evaluated, among other variables, through winning strokes, errors and type of service (Manrique & González-Badillo, 2003; Valldecabres et al., 2017; Gomez-Ruano et al., 2020). In this sense, previous research in world elite games had identified that in the disputing the point, players exchange an average of 7-14 blows, between 6-10 seconds (s) (Torres-Luque et

al., 2019), and, recover for the next point fight at around 23 s of time (Gawin et al., 2015). Also, it was observed that doubles perform shorter rallies compared to singles, except for female doubles which perform long rallies (Torres-Luque et al., 2019; Gawin et al., 2015). Combined with the characterization of the activity profile and performance in games, there is the temporal structure, often investigated via the duration of the match, game and rally, rest time between rallies and work density (Chiminazzo et al., 2018). These data can be obtained by recording videos and researchers use the notational analysis method (Hughes et al., 2007) to sequentially describe the players' behavior throughout the match and in the different phases of a competition.

The results of notational and temporal analysis can reveal differences between the events, whether in the activity profile, in the physical demands imposed by the game, or in performance, bringing evidence that training must be specific (Alcock & Cable, 2009). Although the game profile and performance in badminton have been extensively studied, the available literature brings a small number of studies related to junior and doubles event games: notational analysis studies brought data from singles games and categories between U-15 to U-19, and only one with doubles games, two of which in a simulated context (Fernandez-Fernandez et al., 2014; Ming et al., 2008) and three others in a real game situation. Cabello and Padial (2002) present the data grouped to the main category and under the punctuation system considered as traditional or conventional. Leong and Krasilshchikov (2016) compared juniors' data with the main category, encompassing only the temporal structure and some technical aspect variables, verifying that the main category's game has higher duration values in relation to the juniors'. Istchuk (2016) verified the temporal structure, technical variables, and physiological responses of players in the five Badminton events and observed that the male individual game is more intense, that is, with shots delivered in a smaller fraction of time compared to the female one, however, differences were not found in the doubles game.

There is an agreement about differences in physical abilities between elite main category players versus junior players at any sport (Yuksel et al., 2015). The identification of the game's activity profile and performance are essential for the ideal prescription of competitive training, allowing training not too focused on the development of physical abilities alone (Zemková et al., 2017), considering the integral development of the players, as well as respecting the transition of competitive skill level from juniors to the main category (Leong & Krasilshchikov, 2016). Therefore, the general objective of the present study was to identify the characteristics of the game profile and performance considering notational and temporal variables of junior players at the Pan American level.

## **Methods**

### **Design and samples**

The study design was observational and descriptive supported by the notational analysis method (Anguera and Mendo, 2013). The sample included a total of 277 games and 9,847 rallies from 124 games of the five badminton events of the 28th Pan American Junior Championships 2019 from the U-13 to U-19 categories starting from the quarterfinals, with 60 games in Boys' Singles (BS); 63 games in Girls' Singles (GS); 51 games in Boys' Doubles (BD); 48 games in Girls' Doubles (GD); and 55 games in Mixed Doubles (XD). All matches were played under the 21-point best-of-three-game scoring system (BWF, 2021).

The independent variables were events, games, knockout stage, categories, while the dependent variables were: match/game duration, rally time, real playing time, rest time between rallies, density, % time played, total points played, shots per rally/game, shot frequency rally/game, point outcome performed of the last shot (winner stroke, unforced error, and forced error), and hitting area of the last shot (fault, net, out, and nine zones of court).

The recordings were obtained from the public access platform YouTube™, specifically from the Badminton Pan Am Confederation's official channel ([link](#)).

### **Procedures**

Each game was analyzed using a game analysis tool called Ideal Performance®; its interface allows the reproduction of the video of the match under analysis and the triggering of specific commands to record in spreadsheets the data of the studied variables. Data was collected by an observer with two years of practical experience in badminton. Prior to the registration stage (two months), the main observer received technical-tactical training sessions in badminton and about the use of the tool by an expert (25 years of experience in badminton training), while an external observer trained in badminton (seven years of experience) received training to use the tool. Upon reaching consensual agreement on the study variables between the researcher, the expert and the external observer, the recording were started. The intraobserver and interobserver agreement, using the Kappa Cohen (Landis & Koch, 1977) were considered almost perfect (kappa between 0.95 and 1.00 for intra-observer and 0.92 and 0.99 for inter-observer).

### **Statistical Analysis**

The 3-way Manova was used in the General Linear Models at the identification of the temporal and notational structure for the quantitative variables. Data distributions were tested and the tweedie distribution with log link function was adopted. Multiple comparisons were performed applying Bonferroni corrections. For the nominal-categorical variables, multinomial regression models were performed considering events, games, competition phases and categories as predictors in a generic model established for this analysis. The results of the Omnibus - Chi-square test summarized the effect of the regression model and data from this analysis was presented in a visual model of absolute frequency (heatmap), where the darker color indicates an association between the predictors and the outcome. The established significance level was  $P < 0.05$ .

### **Results**

#### **Results of temporal variables**

Tables 1, 2, 3 and 4 show the temporal and technical-tactical comparisons between the events, games and phases of the competition. Considering the result of the events in a comprehensive way, there were significant differences in most of the contextual scenarios, which correspond to the games and phases of the competition, for all variables, with the exception of the total variable of points played.

#### **Rally Time**

##### *Quarter finals*

- 1 st and 2 nd game: GS presented a longer rally duration than the DGs. BD completed the rallies in shorter duration of time compared to BS, GS and GD.
- 3 rd game: BS rallies were longer compared to BD and XD, and GS had higher rally duration values than BD.

##### *Semifinals*

- 1 st game: BD and XD performed shorter rallies compared to GS, BS and GD point disputes.
- 2 nd game: BD performed short duration rallies compared to GS, BS and BD.

##### *Finals*

- 1 st game: BD and XD performed shorter rallies compared to GS, BS and GD
- 2 nd game: BD had shorter rallies than BS.

- 3rd game: BD had shorter rallies compared to GS. Between games there were significant contrasts in the quarterfinals for the BS with shorter rally duration in the 1st game compared to the 3rd game (see table 1).

## Rest time between rallies

### Quarter finals

- 1st and 2nd game: for the BD and XD events, the rest time was lower than the other events, however, in the 2nd game the GS rested longer compared to the GD.
- 3rd game: GS extended the rest time (longer) compared to XD.

### Semifinals

- 1st game: GS presented a longer rest time than the DG

### Finals

- 1st game: GS presented higher resting time values compared to BS.
- 3rd game: GS rested 16.81 ± 1.18 s compared to BD (11.49 ± 1.14 s) and XD (11.46 ± 1.13 s) (see table 1).

## Density

### Quarter finals

- 1st and 2nd game: 1st and 2nd game: density values were lower for BD and XD compared to other events.
- 3rd game: The density was lower for BD versus BS.

### Semifinals

- 1st and 2nd game: BD and XD showed lower density values in the 1st and 2nd game compared to the other events.

### Finals

- 1st game: For the BD the density value was lower than for the GS, BS and GD, on the other hand the XD density was lower than that of the BS (see table 1).

**Table 1** – 3-way MANOVA in the General Linear Model for comparison of temporal variables per rally between events, games and competition phases, using categories (U13, U15, U17 and U19) as covariates.

## Real time played

### Quarter finals

- 1 st game: During the match, GS kept the shuttlecock in action longer than BD and XD, while BS also kept the shuttlecock in volley longer than BD
- 2 nd game: GS kept the shuttlecock in play for a longer period of time than the doubles events

#### Semifinals

- 1 st game: GS stayed longer in play than BD
- 2 nd game: GS and BS stayed longer in play than BD

#### Finals

- 1 st game: GS was higher than BD (see table 2).

### Percentage time played

#### Quarter finals

- 1 st game: GS, BS e GD presented a higher % of real time played than the BD. Individual events had a higher % of real time played than XD.

#### Semifinals

- 1 st game: GDs achieved a higher % of real time played than the others events. BD performed lower % of real time played than GS and BS.
- 2 nd game: GS and BS had a higher % of real time played compared to BD.

#### Finals

- 1 st game: BS presented a higher % of real time played in relation to BD and XD. GS was superior to BD (see table 2).

### Shots per rally

#### Quarter finals

- 1 st game: The number of shots per rally delivered by the GS was lower compared to the GD
- 2 nd game: GS had a lower number of hits per rally than the GD and XD.

#### Semifinals and finals

- 1st and 2nd game: DGs performed a greater number of strokes per rally than the other events (see table 3).

## Shot frequency per rally

### Quarter finals

- 1st and 2nd games: BD and XD performed higher shot frequency than GD, BS and GS
- 3rd game: BD and XD had a higher frequency of shots compared to the BS and GS.

### Semifinals and finals

- 1st and 2nd games: GD, BD and XD performed higher shot frequency values than the individual events.
- 3rd game: In the finals, BD and XD hit more shots in fractions of a second compared to GS (see table 3).

## Shots and shot frequency per game

### Quarter finals

- 1st and 2nd games: BD and XD had a higher frequency of hits per game compared to GD, BS and GS
- BD and XD showed higher values compared to GS.

### Semifinals

- 1st and 2nd games: the doubles events performed higher shot frequency values per game compared to the individual events
- 3rd game: XD, GD and BS had higher values of frequency of shots per game compared to GS

### Finals

- 1st and 2nd games: the pairs performed higher average values of frequency of shots per game than the individual events. For shots per game there was a contrast only in the 2nd game where GS had a lower value of shots than XD.
- 3rd game: BD and XD presented higher frequencies of shot per game compared to the GS. The BD had higher shot frequencies than the BS (see table 4).

### Total points played

For the total number of points played, no significant differences were found.

### Technical-tactical performance

The heatmap of the characteristic of finalization of the point showed that in all events and games there was a higher frequency of forced error (p≤0.001; X<sub>2</sub>=63.5, see figure 1). When relating it to the target area, it is observed that the errors occurred most of the time with the shuttle being lost to the net or out (p≤0.001; X<sub>2</sub>=207, see figure 2).

## Discussion

The objective of this study was to identify the characteristics of the game profile and performance of junior badminton pan-american players in its five events, considering competition phases and games.

As in previous research, it is observed that male and mixed doubles have a more explosive game characteristic than the other events (Torres-Luque et al., 2019; Gawin et al., 2015), noted by the shorter rallies, greater exchange of shots per second and lower working density value.

Badminton, as consolidated in the literature, has an intermittent structure of physical effort and recovery breaks (Manrique & González-Badillo, 2003), with a highly variable duration (Valdecabres et al., 2017).

If the male and mixed doubles won the point in a few strokes, the female pairs exchanged a greater number of shots to finish the point. From this, it can be said that the event differs from other doubles events, according to the basic assumption already described in previous studies (Torres-Luque et al., 2019; Gawin et al., 2015), which label female players of women's doubles from the main category of the world elite with great defense capacity and offensive construction (Gawin et al., 2015). Therefore, in this regard, the result of the current study indicates a similar characteristic of the youth game to that of the main category.

The real time played was greater for the women's individual, which may be due to the longer duration of the point dispute. This result is not in line with a previous study that observed this characteristic in badminton matches at the Olympic Games with men's singles players compared to women's singles (Abian-Vicen et al., 2013). It can be deduced that there was greater physical demand for the female individual event in the current study, and this generated more rest time between rallies.

For the total variable of points played, there were no differences between the modalities, and this finding corroborates the study by Abian-Vicen et al. (2013) in an Olympic context, with individual events, however, disagrees with the study by Chiminazzo et al. (2018), also with

Olympic players, but from the men's individual, who reported the increase in the total points played when comparing the group stages with knockout.

Regarding the characteristic of finishing the point, in all games and stages of the competition, categories and events, the forced error was frequent, followed by the winning hit. Previous studies, in general, observed only the unforced error and winning shot and identified that the unforced error occurs frequently in the female individual game compared to the male individual game (Abian-Vicen et al., 2013; Gomez et al., 2019), while in juniors of individual sports the unforced error occurs with the same magnitude in both events (Ming et al., 2008). The result found here can be explained in terms of the similarity of the skill level between the players in competition.

The highest prevalence of forced error and winning shots were lost to the net or out, and when conquered, it was observed that players preferred the back corners of the court to send the shuttlecock. In a previous study with juniors, despite investigating simulated games, the characteristic of unforced error was verified when comparing individual events. The point was often lost in both events for the network (Ming et al., 2008), different from what was observed in this study, which were due to forced error.

## **Conclusion**

The present study identified the characteristics of the game activity profile and performance of junior players in the five badminton events. The profiles seem to follow the characteristics revealed in the main category's playing behavior. Regardless of the categories, differences were observed in all variables of both temporal and notational structure, except for the number of points played.

The main limitation of the study was the unavailability of some U-17 (n=5) and U-19 (n=4) doubles games in the semifinal phase of the competition. It is suggested that, in future studies, analysis should be carried out about the finalization characteristic considering the winner and loser of the point/match for a better identification of the player's skill levels. In addition, statistical analysis that find possible associations between the zones of the court with the type of stroke, trajectory of the shuttlecock, position of the player in the finalization and characteristics of the finalization, components which could present more effective performance indicators, as they would show if the player was in the right zone for the ideal shot and in a good technical-tactical position to attack or press the opponent.

As a practical application, the results support the application of training in the ecological and situational approach, which can encourage rich movements that emerge in the game, thus avoiding the application of closed skill exercises only.

The results of this study, via specific scenarios of the match and/or phases of the competition, may imply benefits for the training process of junior groups at the Pan American level, and other skill levels of the same age group. It is suggested the implementation of reduced games and conditioned to the design of the training program, enabling attack and defense training through situations that allow players to explore various solutions in the game context.

## **Research team notes**

1. The objective of analyzing the existing relationship between scored points, the classification obtained by the athletes in the competition and the temporal characteristics was changed to analysis considering the phases and games of the competition.
2. The analysis between games are shown in the tables, but are not described in the results, in order to make the text more succinct.
3. So far, 10 abstracts have been presented at national and international conferences, 3 of which received award as the best paper presentation, 1 paper was published, two course conclusion papers defended, one of them of the course managed by the National Olympic Committee (Brazilian Academy of Coaches) and another from the Faculty of Physical Education of the Federal University of Mato Grosso. The finalization of an academic master's

thesis and the submission of other papers to international journals arising from this work are still in progress.
